

# **A suggestion for encoding Tangut glyphs**

## **–Reporting the development of the “Tangut Cangjie Input Method”-**

KAWASAKI Keigo  
Soongsil University

At first, I must confess that I am almost a novice to the Tangut language, and don't have, as yet, enough knowledge on the previous studies of this language. However, I have had an idea on input methods of the Tangut script on computers, and implemented this idea. I am grateful to have an opportunity of presenting this research. I expect advices from experts in this area.

### **1. Introduction**

In June, 2016, 6125 Tangut letters and 755 Tangut components have been added to Unicode 9.0, which has raised the possibility of computer-aided research of the Tangut script. As for the standard input method of this script, the method by Li Fanwen (李範文) (1997) based on the Four-Corner Method (四角号码) can, as now, be considered to be the closest to such a standard. Yet it cannot be said to be the best choice, because it has many problems,

e.g. that of coincident codes. Therefore, I pursued to develop an ideal input method which will facilitate the computational processing of the Tangut script. For this purpose, I adapted the Cangjie (倉頡) input method, which is a representative example of glyph-based input method, to produce the Tangut Cangjie input method.

The Cangjie input method was developed by Zhu Bangfu (朱邦復), a Taiwanese, in 1970s, to become the origin of glyph-based input methods, and are used in Taiwan, Hong Kong, etc where Traditional Chinese characters are used. Even if one doesn't know the pronunciation, one can input Chinese characters<sup>1</sup> efficiently, based on the glyph alone, so the Cangjie method is my favorite choice in my everyday academic works. The most difficult problem in Chinese character input methods, including pronunciation-based ones, is that of coincident codes. The Cangjie method boasts the lowest ratio of coincident codes, so is extremely efficient in input processes.<sup>2</sup>

When inputting Chinese characters using the Cangjie method, one needs to analyze (折 zhé) them into pre-determined basic components, which are called ‘character-roots’ (字根), amount to 100 or so, and are each assigned to one key among A to Z. Novices have the burden of memorizing all the analyzing patterns, and this is said to be the biggest drawback of this method. Fortunately, the Tangut script was artificially invented in a relatively short period, so is very transparent and analytic, so that the Tangut letters can be

---

\* This work has been carried out as a part of the project ‘Comparison of Hangul and East Asian Scripts’ (leader: PARK Jinho) supported by the National Hangul Museum. This project deals with Phags-pa, Dongba (東巴) and Tangut scripts, and I am in charge of the Tangut script.

<sup>1</sup> At present, Unicode 9.0 contains about 80,000 Chinese characters, which include Traditional, Simplified, Japanese and other variant versions, and the Cangjie method can deal with the entire set. If one needs to deal with historical materials which contain rare characters, or has to distinguish many variants, the Cangjie method is very helpful.

<sup>2</sup> The Cangjie method or its variants are regular champions in competitions which measure typing speed. A highly skilled typist can input 200 characters in a minute.

seen, in a sense, as artificial pseudo-Chinese characters. Therefore, the burden of memorizing analysis patterns is not so heavy. In short, adapting the original Cangjie method to the Tangut script, the result will be probably one easier to learn than the original, close to the ideal input method.

In this talk, I introduce the Tangut Cangjie method, its strengths and applicability, and discuss why the method takes the form which it currently has.

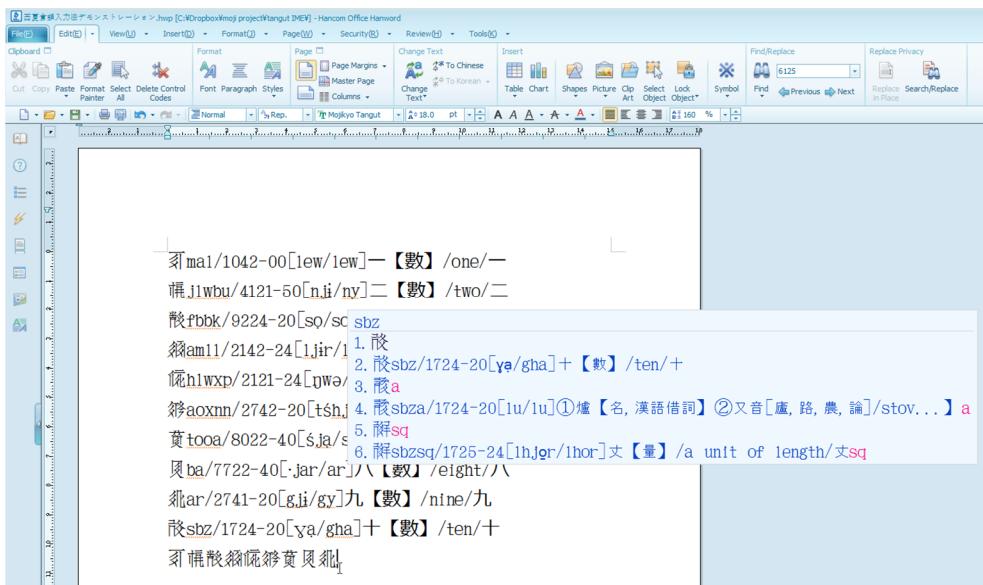

## 2. The Tangut Cangjie Input Method Itself

At first, I will briefly introduce the Tangut Cangjie Input Method in its concrete form. Fig. 1 shows an inputting process, Fig. 2 is the key arrangement, and in Table 1 are some examples of input codes.<sup>3</sup>

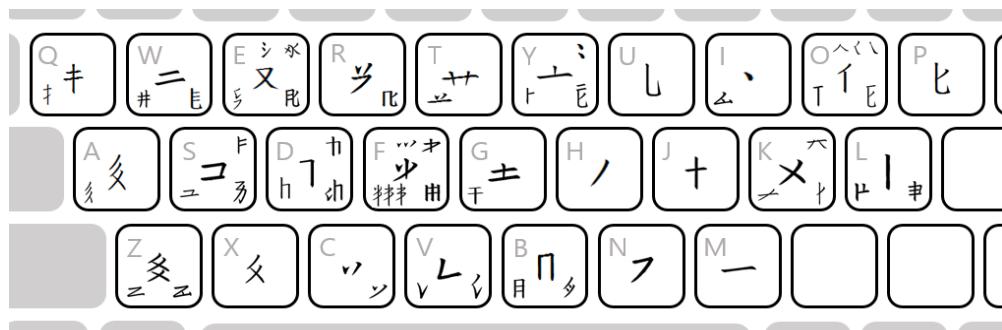

---

<sup>3</sup> As for the Input Method Editor (IME), whatever has been developed for the Cangjie method will work, provided that it can be customized with new code data, and if one is to input Unicode Tangut letters, of course, the IME have to be able to deal with the additional planes in which the Tangut letters are included. In Fig. 1, each candidate letter has much information such as pronunciation, meaning, etc with it. I brought this data from the web site ‘The Complete Collection of Ancient and Modern Characters’ (古今文字集成) (<http://www.ccanc.co/>). The data is as follows: the Tangut letter, input code according to the Tangut Cangjie method / code in Four-Corner Method (四角号码) [ pronunciation reconstructed by Gong Huangcheng (龔煌城) / pronunciation reconstructed by Marc Miyake ] meaning provided in *Abridged Tangut-Chinese Dictionary* (《簡明夏漢字典》) / meaning in English / meaning provided in *Tongyi* (《同義》).

**Fig. 1: Screen capture of an input process using the Tangut Cangjie input method  
(Typing the code 'sbz', one is inputting the letter '𦵃' (+).)**

**Fig. 2: Key arrangement of the Tangut Cangjie input method (v.3)**

**Table 1: Some examples of input codes according to the Tangut Cangjie input method**

|            |     |        |       |       |        |       |       |    |    |     |
|------------|-----|--------|-------|-------|--------|-------|-------|----|----|-----|
|            | 𠂇   | 梩      | 散     | 姁     | 𠂔      | 修     | 薦     | 𠂅  | 𠂆  | 𦥑   |
| Meaning    | 1   | 2      | 3     | 4     | 5      | 6     | 7     | 8  | 9  | 10  |
| Input code | mal | jlwbu  | fbbk  | amll  | hlwxp  | aoxnn | tooa  | ba | ar | sbz |
| Full code  | mal | jlwbwu | fgbbk | amlal | hllwxp | aoxnn | tooba | ba | ar | sbz |

In the Tangut Cangjie input method, at first, the target character is analyzed into components (so-called character roots 字根), and then it is encoded by some letters of the Roman alphabet. This is called ‘full code’. From this full code, according to some rules, at most 5 alphabet letters are drawn. This is called ‘input code’. The rules by which the input code is drawn from the full code, are as follows:

Full code → input code abridging rules

- |  |
|--|
| ① Undecomposable characters<br>→ [1st, 2nd, 3rd, ... Last] (at most 4 letters)   |
| ② Decomposable characters<br>→ [1st ... Last], [1st, 2nd ... Last]<br>(at most 2 letters from the first half, and at most 3 letters from the second)<br>→ [1st ... Last], [[1st ... Last], [... Last]]<br>(If the first half(part) in the second half includes more than two components, then the first and the last component are drawn.) |

Example)

|   | Meaning | Input code | Full code   |
|---|---------|------------|---|
| 𠂇 | 1       | mal        | [ <u>m</u> ] [ <u>a</u> <u>l</u> ]  |
| 𢃥 | 2       | jlwbu      | [ <u>j</u> <u>l</u> ] [ <u>w</u> <u>bwu</u> ]   |
| 𢃥 | 3       | fbbk       | [ <u>f</u> <u>g</u> <u>b</u> ] [ <u>b</u> <u>k</u> ]  |
| 𢃥 | to burn | mtnmu      | [ [ <u>m</u> <u>le</u> ] [ <u>b</u> <u>t</u> ] ] [ [ <u>n</u> <u>t</u> <u>j</u> <u>m</u> ] [ cll ] [ <u>s</u> <u>b</u> <u>u</u> ] ] |

In the case of Tangut characters, there are almost no cases where an undecomposable character is analyzed into more than 4 character-roots, so in fact, one can think of only the rule ②.

Why ‘Cangjie’?

Hitherto, there have been a few attempts to encode Tangut glyphs applicable to inputting, e.g. Four-Corner Method (四角号码) of Li Fanwen (李範文) (1997, 2008, 2012) and N4522 Stroke Order proposed by the Unicode Consortium.

U + 185CF [dzwə/dzwy] 鑷子【名】/tweezers/镊子

N4522 Stroke Order code DCGABBBDGCCQACCQCCCQ (21 strokes)

Four-Corner Method code 8044-40

Tangut Cangjie code RJRXA ← [ R TJ ] [ [ RX ] [ MX A ] ]

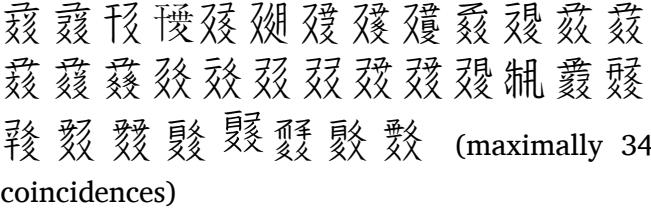

However, the Four-Corner Method has a severe problem of coincident codes (e.g. the code ‘8044-40’ above encodes as many as 9 characters 疣 蔽 蔽 蔽 疝 蔽 蔽 蔽), whereas in the N4522 Stroke Order, codes tend to be too long.<sup>4</sup> For these reasons, both methods are not efficient.

The problem of coincident codes means that input codes corresponding to several different characters happen to be identical. In the Four-Corner method, the worst case is such that one code corresponds to 34 characters, and the average ratio of coincidence is 74%. That is, in three-fourths of cases, after entering the code, one sees more than one candidate appear on the screen, and have to choose one. These candidates can amount to several decades sometimes. On the other hand, in the Tangut Cangjie input method, the worst case is such that one code corresponds to 5 characters, and the average ratio of coincidence is only 14%. The difference is tremendous. Below are some examples of the worst cases of code coincidence. When using these methods to actual inputting, one will easily feel the difference of efficiency.<sup>5</sup>

---

<sup>4</sup> If so, one may think that the N4522 Stroke Order could be improved by introducing code-shortening rules, imitating the full code → input code abridging rules in the Cangjie method. Yet such an attempt would bring about the problem of coincident codes. In order to solve that problem, analysis into so-called character-roots as big as those postulated by the Cangjie method is required anyway. For more detail, see section 5.

<sup>5</sup> Let’s try some simple calculations. As the Four-Corner method uses 6-place digits, theoretically  $10^6 = 1,000,000$  cases can be distinguished. In contrast, as the Tangut Cangjie method uses at most 5 alphabet letters, theoretically  $26 + 26^2 + 26^3 + 26^4 + 26^5 = 12,356,630$  cases can be distinguished. The latter allows over an order of magnitude more patterns than the former.

|   |   |
|---|---|
| Four-Corner<br>method<br>code “1744-00” | <br>(maximally 34 coincidences) |
| Tangut Cangjie<br>method code “sba”     | <br>(maximally 5 coincidences)   |

In addition to the Cangjie method, other glyph-based input methods of Chinese characters include Zhengma (鄭碼入力法), Wubi (五筆字型入力法), Dayi (大易入力法), Boshiamy (嚙蝦米入力法), Hanglie (行列入力法) and so on. When I chose the Cangjie method from these, I based my decision on many factors, such as popularity, simplicity of rules, ratio of coincident codes, and especially smallness of character-roots.<sup>6</sup> The Cangjie method has the smallest and fewest character-roots among them all. According to Zhu Bangfu (朱邦復) (1995), in the Cangjie method ver. 5, there are 114 character-roots, including Cangjie Zimu (倉頡字母) and Supplementary Glyphs (輔助字形). The Tangut Cangjie method has much fewer character-roots, i.e. about 70. Among them, about 40 are shared with the Cangjie method.

As is generally known, the Tangut characters are modelled on Chinese characters, so if an existing input method for Chinese characters could be used to Tangut characters also, that would be the best. Postulating the greatest common denominator between Chinese and Tangut characters as

---

<sup>6</sup> For instance, in the Cangjie method, the character ‘言’(yán) is analyzed into 一(y) + 一(m) + 一(m) + 口(r), and the character ‘車’(chē) into 十(j) + 田(w) + 十(j). The character-roots such as 一(y), 一(m), 十(j) are required in the case of Tangut characters also, but if we postulated Chinese character-like large units such as ‘言’(yán) or ‘車’(chē) as character-roots, then it would be of no use in encoding Tangut characters. In this sense, character-roots should not be too big.

## A suggestion for encoding Tangut glyphs

character-roots would be ideal. In that sense, the Cangjie method is close to that ideal. As the size of the character-roots is appropriate, the Cangjie method can deal with all of the Chinese characters amounting to 80,000, whether Traditional, Simplified or Japanese-style, and for this reason, can also deal with any Chinese character-like script, including the Tangut script.

Lastly, I want to note that the Tangut Cangjie method is much easier to learn than the original Cangjie method. It may be safely said that the Tangut characters are more appropriate than Chinese characters as an object of application of the Cangjie method. The Tangut script was artificially designed in a very short period, unlike Chinese characters, and mostly uses the method of compounding components, so analysis into components is extremely easy. The original Cangjie method is said to have a drawback of having the burden of memorizing the analysis patterns, but when it is adapted to the Tangut script, even such a drawback disappears.

The features (strengths) of the Tangut Cangjie input method can be summarized as follows:

- ① Only using at most 5 Roman alphabet letters (a-z), one can input the entire 6,125 unicode Tangut characters.
- ② The ratio of coincidence is only 14%. That is, 86% of Tangut characters can be inputted even without looking at the screen.
- ③ The number of character-roots is only about 70. About 40 among them are shared with the original Cangjie method.
- ④ In virtue of the analyticity of Tangut characters, the Tangut Cangjie method is much easier to learn than the original Cangjie.

### 3. Further applications of the Tangut Cangjie method

In section 2, I introduced the Tangut Cangjie method from the point of view of input methods. That is clearly the starting point of this work, but this study has more values related to applicability.<sup>7</sup>

What does it mean that you can get the input code and the full code directly and mechanically from the glyphs of Tangut characters? It has two important uses in addition to that of an input method.

⑤ The full codes of the Tangut Cangjie method are a powerful tool for the analysis of glyphs. Using the full codes, one can extract characters which contain a certain component in a second, on the basis of which one can investigate the distribution, meaning and phonological features of components very efficiently.

⑥ The full codes can be used as the ordering keys in dictionaries. They enable automatic arrangement of characters according to semantic determinants (部首). The ratio of coincidence is much lower than the input codes, i.e. 3.7%, and the maximal number of coincidence is 3. These features are clearly strengths compared to the Four-Corner method, which is adopted as the ordering principle in Li Fanwen (李範文) (1997, 2008, 2012), in which the order according to Four-Corner codes has no significance in itself, the ratio of coincidence is much higher (74%), and the maximal number of coincidence is 34.<sup>8</sup>

---

<sup>7</sup> Zhu Bangfu (朱邦復) (1999: 4-11), the inventor of the Cangjie method, already pointed out this fact. He says that input methods are only the first stage or minimal application of his magnificent study.

<sup>8</sup> Of course, before we adopt these Cangjie codes as ordering keys in dictionaries, we must pursue the ideal form of the Tangut Cangjie method, and attempt to standardize the codes. That may cost some time and discussion, but once they have been standardized, they can have various applications as the inherent ordering based only on glyphs.

I will explicate more concretely the point ⑤, i.e. the proposition that the full codes of the Tangut Cangjie method are a powerful tool for the analysis of glyphs. For instance, let's extract all the characters which contain '𢃔' (TCF ho,<sup>9</sup> U + 18841), one of the “Tangut components” of the unicode. Only by searching for the code ‘ho’, one can find the following 54 characters from the 6,125 Tangut characters in one second.

From these characters, you can discern an interesting common feature, i.e. that ‘↑’ always appears in combination with ‘|’ on the righthand side to produce ‘⎮’ (hol, U+18889). Now temporarily postulating three levels “glyph – glypheme – stroke”, parallel to the three levels “word – morpheme – phoneme” in spoken languages, ‘⎮’ corresponds to a “glypheme”, the minimal unit which can have meaning, and ‘↑’ is only a “set of strokes”, which can have no meaning.

Similarly to the above case, I was interested in the difference between ‘𠀤’ (bd, U+1883F) and ‘𠀥’ (bl, U+1883B), i.e. whether they are really distinct, so searched for characters containing these components. As a result, I noticed that the former always appears in the form of ‘𠀤’ (mbd, U+1886E), and the latter always appears in the form of ‘𠀥’ (sbl,

<sup>9</sup> TCF is the abbreviation of ‘Tangut Cangjie Full-code’. In the following, only codes themselves are simply shown.

`U+18939`) or ‘𦨓’ (ssbl, `U+18A30`). That is, the latter three are genuine “glyphemes”, and ‘𦨓’ and ‘𦨔’ are only “sets of strokes”.

In addition, I noticed that the rarely occurring components ‘𢂔’ (il?), ‘𢂕’ (ml?) and ‘𢂖’ (md?, U+1880F) have various forms, lacking uniformity, in existing fonts. So I searched for characters containing the codes ‘il’, ‘ml’ and ‘md’, which had been determined on the basis of mere appearances. Looking at the resultant characters, I found that, in all the characters, the above-mentioned three components always appear on the righthand side of the glypheme ‘𠂇’ (a, U+1888C). On this basis, I concluded that the three are probably just cursive variants of ‘𠂇’ (ao). In the current version, these three are inputted as the standardized code ‘ao’, which resolves the possible inconveniences of inputting. Below are the 32 characters which contain the code ‘ao’. The upper row shows these characters according to the Jing Yongshi (景永時) font, while the lower row according to the Konjaku Mojikyo (今昔文字鏡) font. Note that glyphs lack uniformity.

The above conclusions were arrived at on the basis of analyzing only the two FONTS, so are very tentative, as one has yet to confirm these hypotheses through word meanings or actual linguistic data. In spite of this tentativeness, it is important to note that one can carry out such analysis of glyphs efficiently using full codes of the Tangut Cangjie method.

This possibility of extracting characters containing a certain component, in addition to organization of glyphs, enables further analyses of distribution, meaning and phonological features of components and so on.

#### **4. Design philosophy and differences from the original**

In devising the Tangut Cangjie method, I changed some features of the original Cangjie method, considering properties of Tangut characters. I will explain under what philosophy I made such decisions and why the method has taken the present form in the following.

As said above, it is desirable for the Tangut Cangjie method to basically follow the original Cangjie method in its current form, as the latter is popular and valuable for academic purposes also. Therefore, I followed the character-roots and the key arrangements of the original Cangjie as much as possible in principle, and when there is a need to change the original, one should adhere to the principle of minimizing users' additional burden of memorizing.

Then, let's see where and how I changed the original. Below is the comparison of the character-roots and the key arrangements of the original Cangjie method and the Tangut Cangjie method, which is yet in the developing stage.

Fig. 3: Keyboard map of the original Cangjie method

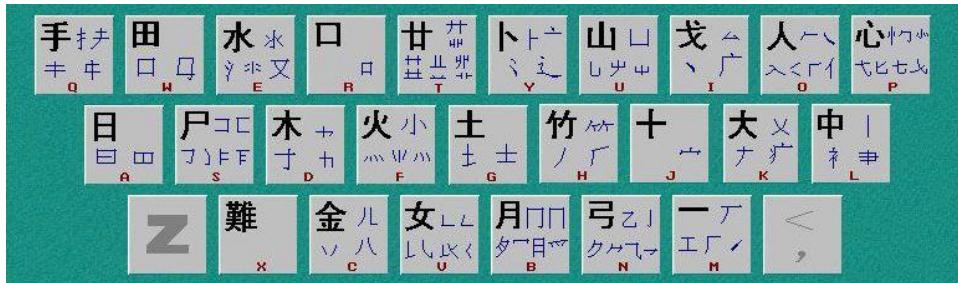

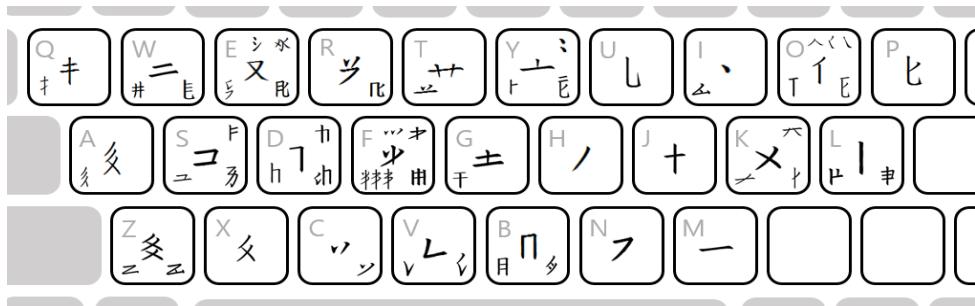

Fig. 4: Keyboard map of the Tangut Cangjie method (version 3)

Firstly, the character-roots assigned to the keys ‘A’(日), ‘R’(口) and ‘W’(田) in the original Cangjie method are not used in Tangut characters at all. The key ‘Z’ was not used in the original, and ‘X’(難) was the special key reserved for the analysis of Chinese characters which are difficult to decompose. As Tangut characters are easy to decompose, such a special key is not needed. For these reasons, if you followed the original Cangjie method as it is, the five keys ‘A’, ‘R’, ‘W’, ‘Z’ and ‘X’ would not be used, which would be a waste of keys.

At the early stages of the development when I tried to follow the original Cangjie method with no change, I found a unique habit in Tangut characters. That is, there are many characters which end with ク (k) or ヲ (p), and

## A suggestion for encoding Tangut glyphs

these caused massive coincidence of codes. This would reduce the most important strength of the Cangjie method, i.e. the low ratio of coincidence.

In order to save the strength of the Cangjie, I needed to disperse these characters by differentiating the ending codes, at the same time minimizing changes. For this purpose, I looked for frequent units somewhat larger than  $\times$  (k) or  $\ell$  (p), postulated such units as additional character-roots, and assigned them to the keys including hitherto unused keys ‘A’, ‘R’, ‘W’, ‘Z’ and ‘X’.

Characters with  $\times$  (k) at the end are dispersed as follows (‘X’, ‘A’ and ‘Z’ are all located at the left-lower part of the keyboard.):

|              | $\times$ | $\times$ <sup>10</sup> | $\times$ <sup>11</sup> | $\times$     | $\times$    | $\times$      |
|--------------|----------|------------------------|------------------------|--------------|-------------|---------------|
| early code   | <u>k</u> | h <u>k</u>             | h <u>hk</u>            | h <u>hhk</u> | h <u>hk</u> | h <u>hkhk</u> |
| changed code | k        | x                      | a                      | ha           | z           | xx            |

Characters with  $\ell$  (p) at the end are dispersed as follows (‘P’, ‘O’, ‘Y’, ‘R’, ‘E’ and ‘W’ are all located at the second row in the keyboard.):

---

<sup>10</sup> We don't distinguish  $\times$  (U+18843),  $\times$  (U+18844) and  $\times$  (U+18845) in the Tangut Cangjie code.

<sup>11</sup> We don't distinguish  $\times$  (U+1888C),  $\times$  (U+1888D), and  $\times$  (U+1888F) either. Also  $\times$  (a, U+1888B) is not distinguished in current version, which actually always appears as a part of  $\times$  (al, U+18905), thus is not a glypheme. On the other hand, we also have a lot of  $\times$  (al)s, composed of a glypheme  $\times$  and |, which means both frequently appearing  $\times$  and  $\times$  are represented by the same code ‘al’ in current version. I am now considering whether we should postulate  $\times$  as a new ‘character-root’ or not.

|              |   |    |          |    |    |    |
|--------------|---|----|----------|----|----|----|
|              | 匕 | 匚  | 匁        | 匂  | 匄  | 匊  |
| early code   | p | mp | mmp(>wp) | bp | bp | sp |
| changed code | p | o  | y        | r  | e  | w  |

Even after the above-mentioned dispersion, the three most-frequently-appearing keys at the end of codes are ‘x’(848), ‘a’(665) and ‘p’(655), which are still making the most coincidences remaining. This fact well proves the validity of the “dispersion” process we took. (Imagine both ‘x’ and ‘a’ were all ‘k’s originally!)

In designing how to disperse, we also need to consider the arrangement and locations of keys in the keyboard, in order to alleviate users’ burden of memory. ‘O’, ‘Y’, ‘E’ etc were already used, but not so heavily, so I chose such keys, which were not to cause much trouble.

The dispersion of  $\times(k)$  and  $\dot{\chi}(p)$  was the point of the first and biggest change in the development process of the Tangut Cangjie method. Afterward, new character-roots were added in order to alleviate the problem of code coincidence or to reflect features of Tangut characters better. In this process, the following principles were adhered to:

- ① Character-roots are assigned to the same key, such that they are as much related to one another as possible, in that one is reminiscent of another.
- ② Newly appearing code coincidences are suppressed as much as possible, on the basis of statistics.

As a result, some character-roots peculiar to the Tangut Cangjie method were postulated, and I got the result of the 14% ratio of coincidence and the maximal code coincidence of 5 characters.

Of course, the current form is not yet complete. Through ongoing testing, I will pursue a more ideal form.

## 5. Concluding remarks

In the above, I introduced the Tangut Cangjie input method, and discussed the significance of encoding glyphs of Tangut characters. This method purports to be an ideal system, easy to learn and efficient as an input method. The full codes, which have been obtained as a by-product of the development, are a powerful tool for analyzing glyphs, which can be used for investigating the distribution, meaning and phonological features of components. In addition, they can be used as ordering keys in dictionaries. This ordering principle has significance in that it automatically arranges characters according to semantic determinants (部首).

An efficient input method helps learners to consult dictionaries efficiently, which is directly related to efficient learning of the Tangut language. Additionally, it will also enable us to build large-scale Tangut-Chinese parallel corpora in unicode texts efficiently. This study is expected to make the learning and treatment of the Tangut script easier, expand the base of researchers, and help the study of the Tangut language and script to progress afterwards.
